

How much BPA does a typical person take in through a normal diet?

Bisphenol A (BPA) has been approved for use as monomer for the production of plastics articles in food contact such as polycarbonate and epoxy resin since 1990. In the most recent European Food Safety Authority's (EFSA) assessment the authority concludes that BPA poses no health risk to consumers of any age group (including unborn children, infants and adolescents) at current exposure levels.¹

How safe is safe? Very safe – because of a built-in safety margin

EFSA applied high Margins of Safety in the derivation of the safety level of Bisphenol A, the so called Tolerable Daily Intake (TDI). On the Human Equivalent Dose (dose of BPA just not causing an adverse effect in animals translated into human organism taking into account kinetic and metabolistic differences) EFSA applied an additional safety factor of 150 to account for variabilities and any potential uncertainties. From that basis the TDI is derived at 4 microgram/kg bodyweight/day.

How small is 8 micrograms?

If a small mint (weighing 800 milligrams) was broken into pieces each of which weighs 8 micrograms, you would have more than 100,000 tiny pieces, the naked eye could barely see.

It would take about 274 years to consume the entire mint if one piece was taken in every day, 365 days a year.

To reach the level of BPA considered safe for a daily lifelong intake one single person weighing 60 kg would have to consume the content of **about 1450 cans of beverages³ every day.**

What happens to BPA inside the human body?

We know a great deal about how BPA is processed by the human body from extensive studies on lab animals and some studies with human volunteers.

The trace amount of BPA that may be taken in through the normal daily diet is far below a level that could cause health effects.

When ingested, BPA is absorbed through the intestinal wall. Most of the BPA that is taken in is converted in the intestine to an inactive metabolite, a kind of sugar, with no known biological activity.

Remaining trace levels of BPA are converted in the liver to the same inactive substance before entering the bloodstream. The inactive sugarcompound is eliminated through urine within 24 hours.

In clinical studies when volunteers were exposed to much higher levels of BPA than typical, no free BPA could be detected in the bloodstream.

Consuming “external” estrogens is part of the normal diet.

We regularly consume naturally occurring estrogen-like substances, called “phytoestrogens”, as part of our diet through vegetables like soy beans, carrots, garlic or coffee. Only in a laboratory it is possible to produce very low estrogen-like activity by exposure to very high levels of BPA which can never be reached in normal daily life.

Even more: **It is virtually impossible for consumers to be exposed to the amount of BPA established as safe limit by European and international authorities via food.**

Comparing ingestion of estrogen-like compounds in 200 g of food and beverages

0.1 microgram \cong 0.04 % of the safe daily intake for a 60 kg person⁴

800 microgram⁵

The estrogen-like potency of BPA is similar to that of naturally occurring estrogen-like substances.

Carrots contain about 8000 times more estrogen-like compounds than the same amount of beverages from epoxy-coated cans.
